Introduction

- $\pi\pi$ and πK scattering are basic strong processes

  Study them as precise as possible
- Earlier: $\pi\pi$ proved that two-flavour case of $\langle \overline{q} q \rangle$
- Three flavour case: works or problems with strange quark loops (in scalar sector)?
- πK excellent place to study this
- Need precise calculations also here

Why (Effective) Field Theory?

Effective:

- Use right degrees of freedom : essence of (most) physics
- Gap in the spectrum $\Longrightarrow$ separation of scales
- With lower d.o.f.: build most general Lagrangian

- $\infty\sharp$ parameters
- Where did predictivity go ?

$\left.\right\} \Longrightarrow$ power counting

Why (Effective) Field Theory?

Field Theory

- Only known way to combine QM and special relativity
- Taylor series does not work (convergence radius zero)
- Continuum of excitation states to be taken into account
- Off-shell effects fully under control: these effects are there as new free parameters
- model-independent and systematic: ALL effects at given order included
- Theory $\Longrightarrow$ errors can be estimated
- Many parameters (but possible modelspace is large)
- Expansion might not converge (often still useful for model classification)

Chiral Perturbation Theory

Degrees of freedom: Goldstone Bosons from Chiral Symmetry Spontaneous Breakdown

Power counting: Dimensional counting

Expected breakdown scale: Resonances, so M_ρ or higher depending on the channel

Chiral Symmetry

QCD: 3 light quarks: equal mass: interchange: $SU(3)_V$

But $$\mathcal{L}_{QCD} = \sum_{q=u,d,s} \left[i\bar{q}_L \not{D} q_L + i\bar{q}_R \not{D} q_R - m_q \left(\bar{q}_R q_L + \bar{q}_L q_R \right) \right]$$

So if $m_q = 0$ then $SU(3)_L \times SU(3)_R$.

Can also see that via  $v < c$, $m_q \neq 0 \Longrightarrow$ 
$v = c$, $m_q = 0 \not\Longrightarrow$

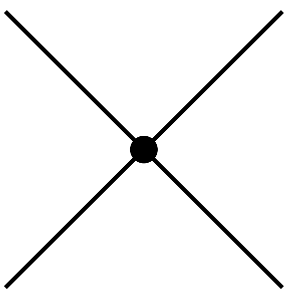
Chiral Perturbation Theory

$\langle \bar{q} q \rangle = \langle \bar{q}_L q_R + \bar{q}_R q_L \rangle \neq 0$

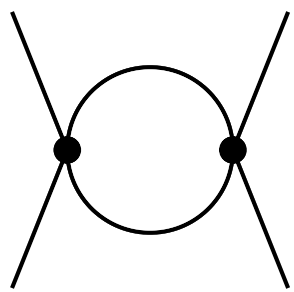
$SU(3)_L \times SU(3)_R$ broken spontaneously to $SU(3)_V$

8 generators broken $\Longrightarrow$ 8 massless degrees of freedom and interaction vanishes at zero momentum

Power counting in momenta:



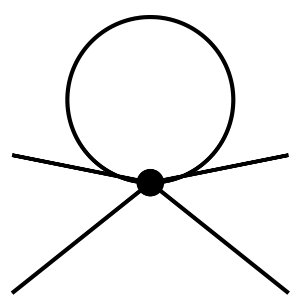
p^2



$(p^2)^2 \, (1/p^2)^2 \, p^4 = p^4$

$1/p^2$

$\int d^4p$ $\quad p^4$



$(p^2) \, (1/p^2) \, p^4 = p^4$

General Strategy and some comments

- Find enough inputs from experiment
- C_i^r:
  - kinematical dependence: agree well with single resonance saturation
  - quark mass+kinematical: if vector dominated, seems to be OK
  - quark mass+kinematical: if scalar dominated: which scalars? (not σ)
  - quark masses: which scalars? unrealistically large estimates
- in p^6 physical or lowest order masses: thresholds in right place requires physical

General Strategy and some comments

- errors are very correlated
- $\mu = 770$ MeV; 550 or 1000 within errors
- varying C_i^r factor 2 about errors
- $L_4^r, L_6^r \approx -0.3, \dots, 0.6\ 10^{-3}$ OK
- fit B: small corrections to pion “sigma” term, fit scalar radius
- fit D: fit $\pi\pi$ and πK thresholds

- Pattern of mass corrections can vary a lot
- F_K/F_π always OK expansion
- $m_u = 0$ always very far from the fits

- F_0: pion decay constant in the chiral limit

Conclusions

Three flavour ChPT at 2 loops doing fine: much progress

- many calculations done
- things seem to work but convergence is fairly slow
- "kinematical" and "vector" C_i^r seem to be OK
- L_4^r, L_6^r nonzero but reasonable for large N_c
- $\eta \to 3\pi$, isobreaking in $K_{\ell 3}$: parts done

πK open problems

- Cleaning up C_i^r contributions and uncertainties
- Properly predicting threshold parameters
