Motivation

• High precision data on leading neutrons produced in electron – proton reaction at HERA at high energies became available.
Motivation

- High precision data on leading neutrons produced in electron – proton reaction at HERA at high energies became available.
Motivation

• High precision data on leading neutrons produced in electron–proton reaction at HERA at high energies became available.

• In spite of intense experimental and theoretical efforts (*), the Feynman momentum distribution of the leading neutrons remains without a satisfactory theoretical description.

• In spite of intense experimental and theoretical efforts, the Feynman momentum distribution of the leading neutrons remains without a satisfactory theoretical description.
• The interpretation of cosmic ray data depends on the accurate knowledge of the leading baryon momentum spectrum and its energy dependence.
• Leading neutron production at high energies probes the low – x component of the target wave function, where nonlinear effects are expected to be present in the description of the QCD dynamics.
Linear QCD evolution equations predict a power growth of gluon distribution as $x \to 0$ (violates unitarity).

Number of gluons in the nucleon becomes so large that gluon recombine $\Rightarrow$ Nonlinear effects

**Saturation scale** $Q_s$ (energy and atomic number dependent) defines the onset of nonlinear QCD dynamics.
Our goal

- Treat the inclusive and exclusive processes with a leading neutron in ep collision using the color dipole formalism (*)

(*) Largely used to successfully describe the HERA data w/o a leading neutron.
Our goal

• Treat the inclusive and exclusive processes with a leading neutron in ep collision using the color dipole formalism.
• Describe the current high precision HERA data.

• Estimate the impact of the nonlinear effects.
Our goal

- Treat the inclusive and exclusive processes with a leading neutron in ep collision using the color dipole formalism.
- Describe the current high precision HERA data.
- Estimate the impact of the nonlinear effects.
- Predict the magnitude of the cross sections for inclusive and exclusive processes with a leading neutron in future electron – proton colliders and in exclusive processes at the LHC.

Photoproduction in $pp$ collisions at LHC probes energies one order of magnitude larger than HERA.
Photon - induced interactions at the LHC

\[ \gamma h \text{ Processes: } \sigma(h_1h_2 \rightarrow X) = n_h(\omega) \otimes \sigma^{\gamma h \rightarrow X}(W_{\gamma h}) \]

- Exclusive processes: \( \gamma p \rightarrow Xp \)

\[ \Rightarrow \text{ Heavy vector meson photoproduction } (X = J/\Psi, \ Upsilon) \]

The final state is characterized by two rapidity gaps

\( (pp \rightarrow p \otimes X \otimes p) \).

- Cross section is proportional to the square of the proton/nuclear gluon distribution.

- Diffractive vector meson photoproduction in UPHIC is a probe of the gluon distribution \(^a\)

Diffractive vector meson photoproduction in UPHIC
Probing the nuclear gluon distribution

Since $x = M_{J/\Psi}/\sqrt{s} \exp(-y)$ we have:

$y = -3 \Rightarrow x = 0.02$

$y = 0 \Rightarrow x = 0.001 \text{ in } xg_A(x, Q^2).$
